Formula: Total Profit = sum(Orders[Revenue]) - sum(Orders[Cost])

The screenshot displays the Microsoft Power BI Desktop interface. At the top, the ribbon includes tabs for File, Home, Insert, Modeling, View, Optimize, Help, Format, Data / Drill, Table tools, and Measure tools. The 'Measure tools' tab is active, showing options for Name (Total Profit), Home table (Orders), Format (General), and Data category (Uncategorized). Below the ribbon, the formula bar contains the measure definition: `1 Total Profit = sum(Orders[Revenue]) - sum(Orders[Cost])`. The main report area shows a table with the following data:

Name	Distinct Customers	Total Profit
ABC Groceries	1	523,317.00
ACME Bites	1	828,379.00
Park & Shop Convenience Stores	1	423,498.50
Tres Delicious	1	302,199.00
Wholesome Foods	1	639,677.00
Total	5	2,717,070.50

On the right side, the 'Data' pane shows a list of fields. Under the 'Orders' table, 'Distinct Customers' is selected. Under the 'Profit' table, 'Total Profit' is selected. The 'Visualizations' pane is empty. The bottom status bar indicates 'Page 1 of 1' and a zoom level of 80%.

Formula: Sum of Revenue minus Sum of Cost = SUM('Orders'[Revenue]) - SUM('Orders'[Cost])

80%

Formula: Profit Margin % = [Total Profit] / sum(Orders[Revenue])

The screenshot displays the Microsoft Power BI Desktop application. At the top, the title bar reads "Untitled - Power BI Desktop". The ribbon includes tabs for File, Home, Insert, Modeling, View, Optimize, Help, Format, Data / Drill, Table tools, and Measure tools. The "Measure tools" tab is active, showing the "Name" field set to "Profit Margin %", the "Format" dropdown set to "Percentage", and the "Data category" dropdown set to "Uncategorized". The "Home table" is set to "Orders".

The main workspace shows a calculated measure formula: `1 Profit Margin % = [Total Profit] / sum(Orders[Revenue])`. Below the formula bar, a table displays the results of the measure:

Cookie Type	Profit Margin %
Chocolate Chip	60%
Fortune Cookie	50%
Oatmeal Raisin	56%
Snickerdoodle	63%
Sugar	58%
White Chocolate Macadamia Nut	54%
Total	58%

On the right side, the "Data" pane shows a search bar and a list of fields. The "Orders" table is expanded, showing fields such as "Chocolate chip with over 500 units", "Cost", "Count of orders", "Customer ID", "Date", "Day of week", "Distinct Customers", "Has Chocolate", "Order ID", "Product", "Profit", "Profit Margin %", "Revenue", "Total Numbers of Cookies Sold", "Total Profit", and "Units Sold". The "Profit Margin %" field is selected and highlighted.

At the bottom left, the status bar indicates "Page 1 of 1". At the bottom right, the zoom level is set to 80%.

Formula: Total Profit 2 = sumx('Cookie Types','Cookie Types'[Units Sold]*('Cookie Types'[Revenue Per Cookie] - 'Cookie Types'[Cost Per Cookie]))

The screenshot displays the Power BI Desktop interface. The top ribbon includes tabs for File, Home, Insert, Modeling, View, Optimize, Help, Format, Data / Drill, Table tools, and Measure tools. The 'Measure tools' tab is active, showing the 'Name' field set to 'Total Profit 2' and the 'Home table' set to 'Cookie Types'. The 'Format' dropdown is set to 'General', and the 'Data category' is 'Uncategorized'. The 'Calculations' section shows 'New measure' and 'Quick measure' buttons.

The main workspace shows the DAX formula for 'Total Profit 2':

```
Total Profit 2 = sumx('Cookie Types','Cookie Types'[Units Sold]*('Cookie Types'[Revenue Per Cookie] - 'Cookie Types'[Cost Per Cookie]))
```

Below the formula, the calculated value is displayed as 2,717,064.38. The 'Data' pane on the right shows the 'Cookie Types' table with columns: Cookie Type, Cost Per Cookie, Revenue Per Cookie, Sum of Revenue minus Sum of Cost, Total Profit 2 (checked), and Units Sold. The 'Orders' table is also visible with columns: Chocolate chip with over 500 units and Cost.

Page 1 of 1

Formula: Day of week = WEEKDAY(Orders[Date],1)

Formula: Chocolate chip with over 500 units = CALCULATE(COUNTROWS(Orders),Orders[Units Sold]>500,Orders[Product]=="Chocolate Chip")

Formula: Profit = Orders[Revenue] - Orders[Cost]

Table: Orders (700 rows) Column: Profit (657 distinct values)

Formula: Profit Margin % = [Total Profit] / sum(Orders[Revenue])

The screenshot displays the Microsoft Power BI Desktop application. The top ribbon includes tabs for File, Home, Insert, Modeling, View, Optimize, Help, Format, Data / Drill, Table tools, and Measure tools. The 'Measure tools' tab is active, showing the 'Name' field set to 'Profit Margin %', the 'Format' dropdown set to 'Percentage', and the 'Data category' dropdown set to 'Uncategorized'. The 'Home table' is set to 'Orders'. The 'Structure' pane on the left shows a table with columns 'Cookie Type' and 'Profit Margin %'. The 'Properties' pane on the right shows the 'Data category' as 'Uncategorized'. The 'Calculations' pane on the right shows the 'New measure' button. The main report area displays a table with the following data:

Cookie Type	Profit Margin %
Chocolate Chip	60%
Fortune Cookie	50%
Oatmeal Raisin	56%
Snickerdoodle	63%
Sugar	58%
White Chocolate Macadamia Nut	54%
Total	58%

The 'Data' pane on the right shows a search bar and a list of fields. The 'Orders' table is expanded, showing fields like 'Chocolate chip with over 500 units', 'Cost', 'Count of orders', 'Customer ID', 'Date', 'Day of week', 'Distinct Customers', 'Has Chocolate', 'Order ID', 'Product', 'Profit', 'Profit Margin %', 'Revenue', 'Total Numbers of Cookies Sold', 'Total Profit', and 'Units Sold'. The 'Profit Margin %' field is selected.

Page 1 of 1

Formula: Total Profit 2 = sumx('Cookie Types','Cookie Types'[Units Sold]*('Cookie Types'[Revenue Per Cookie] - 'Cookie Types'[Cost Per Cookie]))

The screenshot displays the Microsoft Power BI Desktop interface. The top ribbon includes tabs for File, Home, Insert, Modeling, View, Optimize, Help, Format, Data / Drill, Table tools, and Measure tools. The 'Measure tools' tab is active, showing options for Name (Total Profit 2), Home table (Cookie Types), Format (General), and Data category (Uncategorized). The main formula bar contains the following DAX formula:

```
1 Total Profit 2 = sumx('Cookie Types','Cookie Types'[Units Sold]*('Cookie Types'[Revenue Per Cookie] - 'Cookie Types'[Cost Per Cookie]))
```

Below the formula bar, the result of the measure is displayed as a table with one row:

Total Profit 2
2,717,064.38

The right-hand pane shows the 'Data' section with a search bar and a list of fields. The 'Cookie Types' table is expanded, showing fields: Cookie Type, Cost Per Cookie, Revenue Per Cookie, Sum of Revenue minus Sum of Cost, Total Profit 2 (selected), and Units Sold. The 'Customers' table is also expanded, showing fields: Address, City, Country, Customer ID, Name, Notes, Phone, State, and Zip. The 'Orders' table is expanded, showing fields: Chocolate chip with over 500 units, Cost, and an empty row.

Guided Questions:

I. Foundational Concepts

1. Defining DAX: In your own words, how would you explain the difference between a standard Excel formula and a Data Analysis Expression (DAX) based on the tutorial?

Answer: A standard Excel formula works on a fixed cell or range it's static and tied to a specific location in a spreadsheet. DAX, on the other hand, is designed to work with relational data models and entire columns or tables. Instead of referencing "cell B2," DAX references "the Sales Amount column in the Sales table." It's also dynamic it responds to filters, slicers, and visuals automatically, something Excel formulas can't do natively in the same way.

Guided Questions:

I. Foundational Concepts

2. The "Why" of DAX: Why can't we just use the raw numbers from our imported dataset to create complex reports? What is the specific "gap" that DAX fills in Power BI?

Answer: Raw numbers from an imported dataset are just stored values they can't adapt to context. The gap DAX fills is dynamic calculation. For example, raw data might have individual sales rows, but to get "Total Sales only for a specific region when a slicer is clicked," you need DAX. It allows you to create calculations that respond to user interaction and filter context in real time, which raw data simply cannot do.

II. Calculated Columns vs. Measures

3. The Storage Difference: The video demonstrates creating both Calculated Columns and Measures. Which one actually increases the file size of your Power BI model, and why is this an important consideration for large datasets?

Answer: Calculated Columns increase the file size because they are computed row-by-row at data refresh time and stored physically inside the data model. Every new row gets a new computed value saved to memory. Measures, by contrast, are calculated on the fly only when a visual needs them nothing is stored. For large datasets with millions of rows, using Calculated Columns unnecessarily can dramatically bloat your .pbix file.

Guided Questions:

II. Calculated Columns vs. Measures

4. Context Clues: * When you created a Calculated Column, the calculation happened row-by-row.

- **When you created a Measure, the result changed depending on which filters or visuals you clicked.**
- **Question: Explain how "Filter Context" affects the result of a Measure in your final dashboard.**

Answer: Filter Context is the set of filters currently active in a report from slicers, visual filters, row/column headers in a matrix, or cross-filtering from other visuals. A Measure's result automatically adjusts based on whatever Filter Context surrounds it. For example, a Total Sales measure will return the overall total on an empty canvas, but if you place it inside a chart broken down by Region, it will return the sales per region the same formula, different results, because the Filter Context changed. This makes Measures incredibly powerful and flexible.

Guided Questions:

III. Function Application & Syntax

5. The RELATED Function: In the tutorial, the RELATED function is used. Why is this function necessary when working with multiple tables, and what must be established in the Model View for this function to work correctly?

Answer:RELATED is necessary when you need to pull a value from a different table into a Calculated Column. Since Power BI works with relational tables (not one big flat sheet), columns from other tables aren't directly accessible in a formula. For RELATED to work, a relationship must be established in Model View between the two tables specifically, a one-to-many relationship where the table you're pulling from is on the "one" side. Without that relationship, RELATED has no path to follow and will throw an error.

Guided Questions:

III. Function Application & Syntax

6. Deconstructing the Formula: Look at the following formula from the video:

Component	Value
Measure Name	Total Sales
Function	SUM()
Table	Sales
Column	Sales Amount

Total Sales = SUM(Sales[Sales Amount]) Identify the Measure Name, the Function, the Table, and the Column. Why is it "best practice" to include the table name in the reference?

Answer: Total Sales = SUM(Sales[Sales Amount])

Guided Questions:

III. Function Application & Syntax

6. Deconstructing the Formula: Look at the following formula from the video:

Total Sales = SUM(Sales[Sales Amount]) Identify the Measure Name, the Function, the Table, and the Column. Why is it "best practice" to include the table name in the reference?

Answer: Including the table name (Sales[Sales Amount] instead of just [Sales Amount]) is best practice because it removes ambiguity if multiple tables have a column named "Sales Amount," DAX knows exactly which one you mean. It also makes formulas easier to read, debug, and maintain.

Guided Questions:

IV. Analysis & Troubleshooting

7. Data Interpretation: Look at the visual you created using your DAX measures. If the "Total Profit" measure shows a negative number for a specific category, does that mean the DAX formula is "broken," or is it telling you something about the business data? How can you verify which it is?

Answer: A negative "Total Profit" does not mean the formula is broken it's most likely telling you something real about the business: that category is operating at a loss (costs exceed revenue). To verify, you should:

- Check the underlying data for that category (are the cost values higher than the sales values?)
- Simplify the measure temporarily to display just Total Revenue and Total Cost separately to see both sides
- Cross-check with the source dataset to confirm the raw numbers match

Guided Questions:

IV. Analysis & Troubleshooting

8. Optimization: If you were tasked with calculating Profit Margin Percentage, would it be more efficient to create a Calculated Column for every row or a single Measure? Justify your answer based on what you learned about DAX efficiency.

Answer: A single Measure is far more efficient. Here's why:

- A Calculated Column would compute and store the profit margin for every single row in the table, consuming memory and increasing file size even for rows you may never display.
- A Measure calculates the profit margin only when needed, and it automatically adapts to whatever filter context is active (e.g., per product, per region, per month).
- Profit Margin is an aggregated insight, so it makes far more sense as a Measure: Profit Margin % = `DIVIDE([Total Profit], [Total Sales], 0)` clean, dynamic, and storage-efficient.
